Assignment 05 - Views

Intro

This week we learned about Views, Functions, and Stored Procedures. These are all different ways to encapsulate data that is in the database without actually disturbing the database.

When to Use a SQL View

A view is a SQL statement that presents that data in a table. It helps simplify and wrap up the complexity of the query. A huge part of views are to restrict who can and can't access the database in areas where the data is sensitive. Views act as a layer in between the user and the database.

Differences and Similarities Between a View, Function, and Stored Procedure

Views: A View is similar to a virtual table and they do not change much. They are the simplest way to view data through a filter of the database. They work great when you want to do simple reporting.

Function: A Function is a reusable formula that can show scalar values, tables and can also accept parameters. It is similar to a view because it shows that data can be reused but it is best used in situations where filtering or calculations are involved as it can't result in nulls.

Store Procedures: A Stored Procedure something that can be used to change the data in a view. This is the one that can perform Inserts, Update, and Delete.

Summary

Similarities

All in all, views are a great way to create a window into the database. They all offer a way to access the data in a controlled manner. It is easier to maintain a

database through views rather than having everyone manipulate the database. Even in the assignment, making the different views enabled me to be more efficient in how I code since I could take similar SQL statements and manipulate them to my needs in similar tables.
